

Which version of order value are we using?

Finance and operations can use the same dataset and still arrive at different answers. The difference may not be an error. One team may be counting product value, another may include freight, another may use customer payment records, and another may exclude orders that never completed. The useful question is not simply, “Which number is right?” It is:

Which number answers the decision we are trying to make?

Executive Summary

Which version of order value are we using?

Recorded payment value is higher than product value plus freight, but the net difference does not tell the whole story. Positive and negative order-level mismatches partly cancel each other when viewed only as a total.

This matters because finance may see a relatively small reconciliation gap, while operations may still be dealing with a much larger population of orders that require explanation. The useful reporting view needs to show both the net position and the exceptions underneath it. The numbers are not necessarily wrong. They are answering different versions of the question.

1158

Orders requiring Reconciliation Review

Business Question

When finance and operations discuss order value, are they using the same population, the same value definition and the same point in the order lifecycle?

- This review asks:
- Does recorded payment value reconcile to product value plus freight?
 - How large is the net difference?
 - How much order-level mismatch is hidden by offsetting differences?
 - Which payment methods or order statuses explain the exceptions?
 - Are cancelled and unavailable orders still included in any headline totals?

Where does the reconciliation difference sit?

In total, 1158 orders show a difference between product plus freight value and the amount recorded as payment.

The total difference alone does not explain what action is needed. Some orders show a payment value above the recorded order value. Others were delivered even though the recorded payment value remains below it.

These are different reconciliation questions and should not be treated as one exception group.

Recorded Payment Value above Product plus Freight Value

1066 Orders with Payment Value above Order Value	165.66K Positive Reconciliation Difference	155.41 Avg Positive Difference per Order
---	---	---

Recorded Payment Value below Product plus Freight Value

91 Delivered Orders Payment Below Order Value	343.05 Delivered Payment Shortfall Value
--	---

These orders require a different review as the operational process shows them as delivered, while the payment record remains below product plus freight value.

35 Delivered Shortfall Orders - Single Instalment	76.67 Delivered Shortfall Value - Single Instalment	55 Delivered Shortfall Orders - Multiple Instalments	122.92 Delivered Shortfall Value - Multiple Instalments	1 Delivered Shortfall Orders - No Instalment Detail	143.46 Delivered Shortfall Value - No Instalment Detail
--	--	---	--	--	--

The delivered shortfall group can then be separated by the recorded instalment detail.

Orders linked to a single instalment may warrant earlier review because the payment structure does not immediately explain the difference. Orders linked to multiple instalments need additional payment context before the difference is treated as an exception requiring action.

One delivered order had no instalment detail recorded. That record should be reviewed separately, and the process may benefit from a validation check to prevent missing instalment information.

The purpose of the split is not to prove that an order is unpaid. It is to help finance and operations decide which records need attention first, which need more context, and which may reflect a data-quality issue.
